

Wideband, Unity-Gain Stable, JFET-Input OPERATIONAL AMPLIFIER

FEATURES

- **HIGH BANDWIDTH:** 650MHz ($G = +1V/V$)
- **HIGH SLEW RATE:** 2550V/ μ s (4V Step)
- **EXCELLENT THD:** –78dBc at 10MHz
- **LOW INPUT VOLTAGE NOISE:** 8.9nV/ $\sqrt{\text{Hz}}$
- **FAST OVERDRIVE RECOVERY:** 8ns
- **FAST SETTLING TIME (1% 4V Step):** 8ns
- **LOW INPUT OFFSET VOLTAGE:** $\pm 1\text{mV}$
- **LOW INPUT BIAS CURRENT:** $\pm 10\text{pA}$
- **HIGH OUTPUT CURRENT:** 70mA

APPLICATIONS

- **HIGH-IMPEDANCE DATA ACQUISITION INPUT AMPLIFIER**
- **HIGH-IMPEDANCE OSCILLOSCOPE INPUT AMPLIFIER**
- **WIDEBAND PHOTODIODE TRANSIMPEDANCE AMPLIFIER**
- **WAFER SCANNING EQUIPMENT**

DESCRIPTION

The OPA659 combines a very wideband, unity-gain stable, voltage-feedback operational amplifier with a JFET-input stage to offer an ultra-high dynamic range amplifier for high impedance buffering in data acquisition applications such as oscilloscope front-end amplifiers and machine vision applications such as photodiode transimpedance amplifiers used in wafer inspection.

The wide 650MHz unity-gain bandwidth is complemented by a very high 2550V/ μ s slew rate.

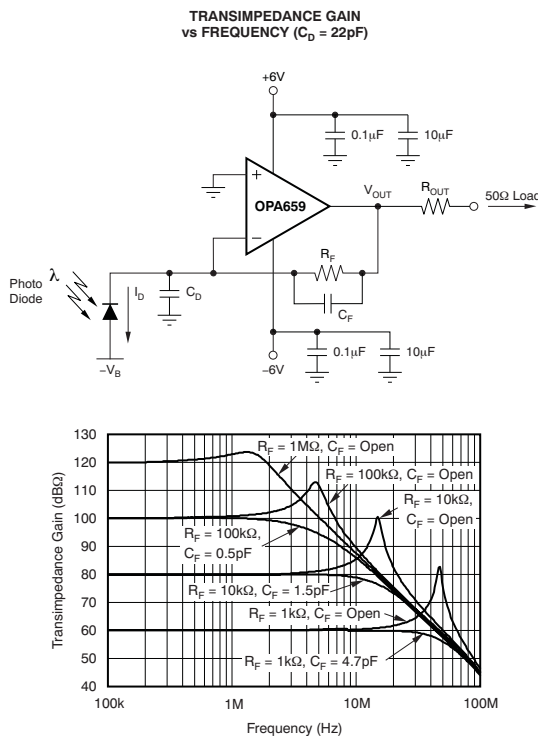

The high input impedance and low bias current provided by the JFET input are supported by the low 8.9nV/ $\sqrt{\text{Hz}}$ input voltage noise to achieve a very low integrated noise in wideband photodiode transimpedance applications.

Broad transimpedance bandwidths are possible with the high 350MHz gain bandwidth product of this device.

Where lower speed with lower quiescent current is required, consider the [OPA656](#). Where unity-gain stability is not required, consider the [OPA657](#).

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PowerPAD is a trademark of Texas Instruments.

All other trademarks are the property of their respective owners.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of the Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

APPLICATION INFORMATION

Wideband, Noninverting Operation

The OPA659 is a very broadband, unity-gain stable, voltage-feedback amplifier with a high impedance JFET-input stage. Its very high gain bandwidth product (GBP) of 350MHz can be used to either deliver high signal bandwidths for low-gain buffers, or to deliver broadband, low-noise, transimpedance bandwidth to photodiode-detector applications. The OPA659 is designed to provide very low distortion and accurate pulse response with low overshoot and ringing. To achieve the full performance of the OPA659, careful attention to printed circuit board (PCB) layout and component selection are required, as discussed in the remaining sections of this data sheet.

Figure 34 shows the noninverting gain of +1 circuit; Figure 35 shows the more general circuit used for other noninverting gains. These circuits are used as the basis for most of the noninverting gain [Typical Characteristics](#) graphs. Most of the graphs were characterized using signal sources with 50Ω driving impedance, and with measurement equipment presenting a 50Ω load impedance. In Figure 34, the shunt resistor R_T at V_{IN} should be set to 50Ω to match the source impedance of the test generator and cable, while the series output resistor, R_{OUT} , at V_{OUT} should also be set to 50Ω to provide matching impedance for the measurement equipment load and cable. Generally, data sheet voltage swing specifications are measured at the output pin, V_{OUT} , in Figure 34 and Figure 35.

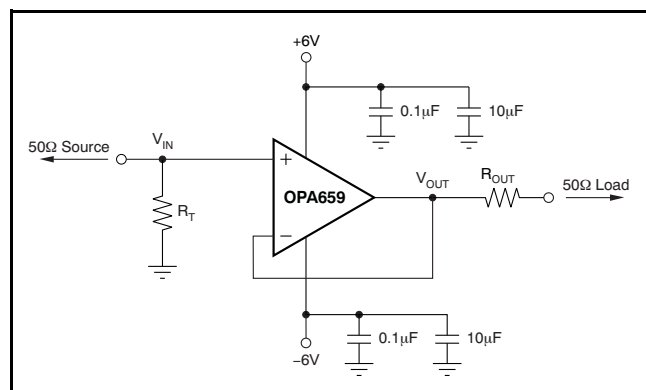

Figure 34. Noninverting Gain of +1 Test Circuit

Voltage-feedback op amps can use a wide range of resistor values to set the gain. To retain a controlled frequency response for the noninverting voltage amplifier of Figure 35, the parallel combination of $R_F \parallel R_G$ should always be less than 200Ω. In the noninverting configuration, the parallel combination of $R_F \parallel R_G$ forms a pole with the parasitic input and board layout capacitance at the inverting input of the OPA659. For best performance, this pole should be at a frequency greater than the closed-loop bandwidth for the OPA659. For this reason, a direct short from the output to the inverting input is recommended for the unity-gain follower application. Table 1 lists several recommended resistor values for noninverting gains with a 50Ω input/output match.

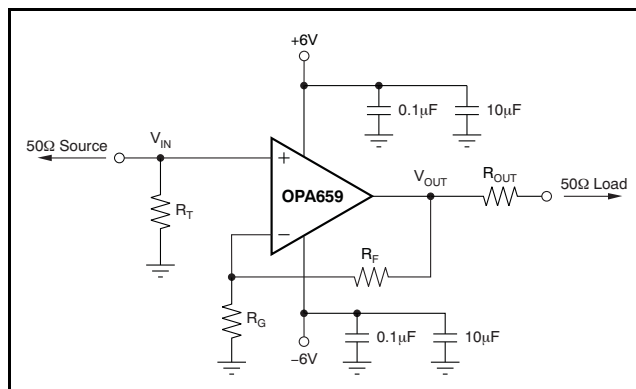

Figure 35. General Noninverting Test Circuit

Table 1. Resistor Values for Noninverting Gains with 50Ω Input/Output Match

| NONINVERTING GAIN | R_F | R_G | R_T | R_{OUT} |
|-------------------|-------|-------|-------|-----------|
| +1 | 0 | Open | 49.9 | 49.9 |
| +2 | 249 | 249 | 49.9 | 49.9 |
| +5 | 249 | 61.9 | 49.9 | 49.9 |
| +10 | 249 | 27.4 | 49.9 | 49.9 |

Wideband, Inverting Gain Operation

The circuit of [Figure 36](#) shows the inverting gain test circuit used for most of the inverting [Typical Characteristics](#) graphs. As with the noninverting applications, most of the curves were characterized using signal sources with 50Ω driving impedance, and with measurement equipment that presents a 50Ω load impedance. In [Figure 36](#), the shunt resistor R_T at V_{IN} should be set so the parallel combination of the shunt resistor and R_G equals 50Ω to match the source impedance of the test generator and cable, while the series output resistor R_{OUT} at V_{OUT} should also be set to 50Ω to provide matching impedance for the measurement equipment load and cable. Generally, data sheet voltage swing specifications are measured at the output pin, V_{OUT} , in [Figure 36](#).

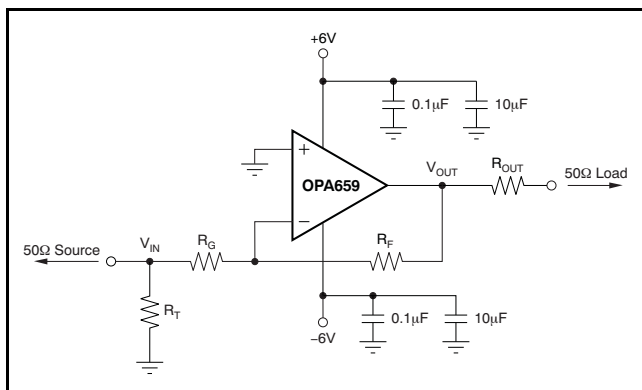

Figure 36. General Inverting Test Circuit

The inverting circuit can also use a wide range of resistor values to set the gain; [Table 2](#) lists several recommended resistor values for inverting gains with a 50Ω input/output match.

Table 2. Resistor Values for Inverting Gains with 50Ω Input/Output Match

| INVERTING GAIN | R_F | R_G | R_T | R_{OUT} |
|----------------|-------|-------|-------|-----------|
| -1 | 249 | 249 | 61.9 | 49.9 |
| -2 | 249 | 124 | 84.5 | 49.9 |
| -5 | 249 | 49.9 | Open | 49.9 |
| -10 | 499 | 49.9 | Open | 49.9 |

[Figure 36](#) shows the noninverting input tied directly to ground. Often, a bias current-cancelling resistor to ground is included here to nullify the dc errors caused by input bias current effects. For a JFET input op amp such as the OPA659, the input bias currents are so low that dc errors caused by input bias currents are negligible. Thus, no bias current-cancelling resistor is recommended at the noninverting input.

Wideband, High-Sensitivity, Transimpedance Design

The high GBP and low input voltage and current noise for the OPA659 make it an ideal wideband, transimpedance amplifier for low to moderate transimpedance gains. Higher transimpedance gains (above 100kΩ) can benefit from the low input noise current of a JFET input op amp such as the OPA659. Designs that require high bandwidth from a large area detector can benefit from the low input voltage noise for the OPA659. This input voltage noise is peaked up over frequency by the diode source capacitance, and in many cases, may become the limiting factor to input sensitivity. The key elements to the design are the expected diode capacitance (C_D) with the reverse bias voltage ($-V_B$) applied, the desired transimpedance gain, R_F , and the GBP for the OPA659 (350MHz). [Figure 37](#) shows a general transimpedance amplifier circuit, or TIA, using the OPA659. Given the source diode capacitance plus parasitic input capacitance for the OPA659, the transimpedance gain, and known GBP, the feedback capacitor value, C_F , may be calculated to avoid excessive peaking in the frequency response.

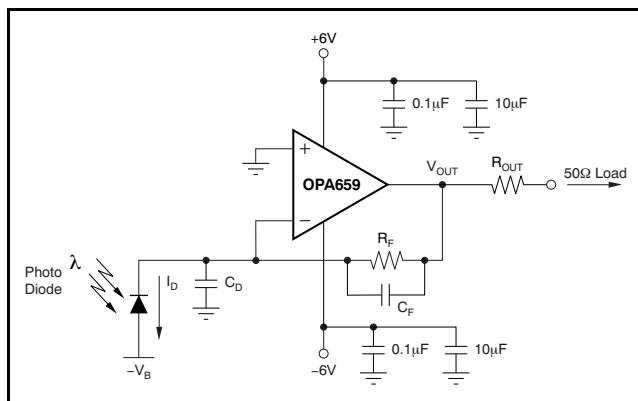

Figure 37. Wideband, Low-Noise, Transimpedance Amplifier (TIA)

To achieve a maximally flat second-order Butterworth frequency response, the feedback pole should be set to:

$$\frac{1}{2\pi R_F C_F} = \sqrt{\frac{GBP}{4\pi R_F C_D}} \quad (1)$$

For example, adding the common mode and differential mode input capacitance (0.7 + 2.8 = 3.5)pF to the diode source with the 20pF capacitance, and targeting a 100kΩ transimpedance gain using the 350MHz GBP for the OPA659, requires a feedback pole set to 3.44MHz. This pole in

turn requires a total feedback capacitance of 0.46pF. Typical surface mount resistors have a parasitic capacitance of 0.2pF, leaving the required 0.26pF value to achieve the required feedback pole. This calculation gives an approximate 4.9MHz, –3dB bandwidth computed by:

$$f_{-3dB} = \sqrt{\frac{GBP}{2\pi R_F C_D}} \quad (2)$$

Table 3 lists the calculated component values and –3dB bandwidths for various TIA gains and diode capacitance.

Table 3. OPA659 TIA Component Values and Bandwidth for Various Diode Capacitance and Gains

OPERATING SUGGESTIONS

Setting Resistor Values to Minimize Noise

The OPA659 provides a very low input noise voltage. To take full advantage of this low input noise, designers must pay careful attention to other possible noise contributors. Figure 38 shows the op amp noise analysis model with all the noise terms included. In this model, all the noise terms are taken to be noise voltage or current density terms in either nV/√Hz or pA/√Hz.

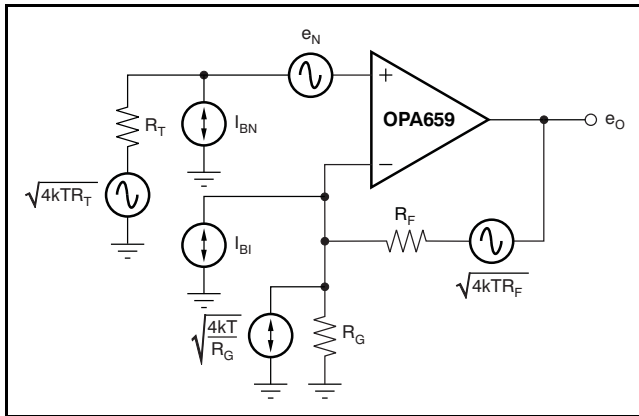

Figure 38. Op Amp Noise Analysis Model

The total output spot noise voltage can be computed as the square root of the squared contributing terms to the output noise voltage. This computation adds all the contributing noise powers at the output by superposition, then takes the square root to arrive at a spot noise voltage. Equation 3 shows the general form for this output noise voltage using the terms shown in Figure 38.

$$e_o = \sqrt{[4kTR_T + (I_{BN}R_T)^2 + e_N^2] \left[1 + \frac{R_F}{R_G}\right]^2 + (I_{BI}R_F)^2 + 4kTR_F \left[1 + \frac{R_F}{R_G}\right]} \quad (3)$$

Dividing this expression by the noise gain ($G_N = 1 + R_F/R_G$) gives the equivalent input-referred spot noise voltage at the noninverting input, as Equation 4 shows.

$$e_{NI} = \sqrt{4kTR_T + (I_{BN}R_T)^2 + e_N^2 + \left[\frac{I_{BI}R_F}{\text{Noise Gain}}\right]^2 + \left[\frac{4kTR_F}{\text{Noise Gain}}\right]} \quad (4)$$

Putting high resistor values into Equation 4 can quickly dominate the total equivalent input-referred noise. A source impedance on the noninverting input of 5kΩ adds a Johnson voltage noise term equal to that of the amplifier alone (8.9nV/√Hz). While the JFET input of the OPA659 is ideal for high source impedance applications in the noninverting configuration of Figure 34 or Figure 35, both the overall bandwidth and noise are limited by high source impedances.

Frequency Response Control

Voltage-feedback op amps such as the OPA659 exhibit decreasing signal bandwidth as the signal gain increases. In theory, this relationship is described by the gain bandwidth product (GBP) shown in the Electrical Characteristics. Ideally, dividing the GBP by the noninverting signal gain (also called the Noise Gain, or NG) can predict the closed-loop bandwidth. In practice, this guideline is valid only when the phase margin approaches 90 degrees, as it does in high gain configurations. At low gains (with increased feedback factors), most high-speed amplifiers exhibit a more complex response with lower phase margins. The OPA659 is compensated to give a maximally-flat frequency response at a noninverting gain of +1 (see Figure 34). This compensation results in a typical gain of +1 bandwidth of 650MHz, far exceeding that predicted by dividing the 350MHz GBP by 1. Increasing the gain causes the phase margin to approach 90 degrees and the bandwidth to more closely approach the predicted value of (GBP/NG). At a gain of +10, the OPA659 shows the 35MHz bandwidth predicted using the simple formula and the typical GBP of 350MHz. Unity-gain stable op amps such as the OPA659 can also be band-limited in gains other than +1 by placing a capacitor across the feedback resistor. For the noninverting configuration of Figure 35, a capacitor across the feedback resistor decreases the gain with frequency down to a gain of +1. For instance, to band-limit a gain of +2 design to 20MHz, a 32pF capacitor can be placed in parallel with the 249Ω feedback resistor. This configuration, however, only decreases the gain from 2 to 1. Using a feedback capacitor to limit the signal bandwidth is more effective in the inverting configuration of Figure 36. Adding that same capacitance to the feedback of Figure 36 sets a pole in the signal frequency response at 20MHz, but in this case it continues to attenuate the signal gain to less than 1. Note, however, that the noise gain of the circuit is only reduced to a gain of 1 with the addition of the feedback capacitor.

Driving Capacitive Loads

One of the most demanding, and yet very common, load conditions for an op amp is capacitive loading. The OPA659 is very robust, but care should be taken with light loading scenarios so that output capacitance does not decrease stability and increase closed-loop frequency response peaking when a capacitive load is placed directly on the output pin. When the amplifier open-loop output resistance is considered, this capacitive load introduces an additional pole in the signal path that can decrease the phase margin. Several external solutions to this problem have been suggested. When the primary considerations are frequency response flatness, pulse response fidelity, and/or distortion, the simplest and most effective solution is to isolate the capacitive load from the feedback loop by inserting a series isolation resistor, R_{ISO} , between the amplifier output and the capacitive load. In effect, this resistor isolates the phase shift from the loop gain of the amplifier, thus increasing the phase margin and improving stability. The [Typical Characteristics](#) show the recommended R_{ISO} versus capacitive load and the resulting frequency response with a 1k Ω load (see [Figure 24](#)). Note that larger R_{ISO} values are required for lower capacitive loading. In this case, a design target of a maximally-flat frequency response was used. Lower values of R_{ISO} may be used if some peaking can be tolerated. Also, operating at higher gains (instead of the +1 gain used in the [Typical Characteristics](#)) requires lower values of R_{ISO} for a minimally-peaked frequency response. Parasitic capacitive loads greater than 2pF can begin to degrade the performance of the OPA659. Moreover, long PCB traces, unmatched cables, and connections to multiple devices can easily cause this value to be exceeded. Always consider this effect carefully, and add the recommended series resistor as close as possible to the OPA659 output pin (see the [Board Layout](#) section).

With heavier loads (for example, the 100 Ω load presented in the test circuits and used for testing typical characteristic performance), the OPA659 is very robust; R_{ISO} can be as low as 10 Ω with capacitive loads less than 5pF and continue to show a flat frequency response.

Distortion Performance

The OPA659 is capable of delivering a low distortion signal at high frequencies over a wide range of gains. The distortion plots in the [Typical Characteristics](#) show the typical distortion under a wide variety of conditions. Generally, until the fundamental signal reaches very high frequencies or powers, the second harmonic dominates the distortion with a negligible third harmonic component. Focusing then on the second harmonic, increasing the load impedance improves distortion directly. Remember that the total load includes the feedback network: in the noninverting configuration, this network is the sum of $R_F + R_G$, while in the inverting configuration the network is only R_F (see [Figure 35](#)). Increasing the output voltage swing directly increases harmonic distortion. A 6dB increase in output swing generally increases the second harmonic by 12dB and the third harmonic by 18dB. Increasing the signal gain also increases the second-harmonic distortion. Again, a 6dB increase in gain increases the second and third harmonics by about 6dB, even with a constant output power and frequency. Finally, the distortion increases as the fundamental frequency increases because of the rolloff in the loop gain with frequency. Conversely, the distortion improves going to lower frequencies, down to the dominant open-loop pole at approximately 300kHz.

Note that power-supply decoupling is critical for harmonic distortion performance. In particular, for optimal second-harmonic performance, the power-supply high-frequency 0.1 μ F decoupling capacitors to the positive and negative supply pins should be brought to a single point ground located away from the input pins.

The OPA659 has an extremely low third-order harmonic distortion. This characteristic also shows up in the two-tone, third-order intermodulation spurious (IMD3) response curves (see [Figure 19](#)). The third-order spurious levels are extremely low (less than -100 dBc) at low output power levels and frequencies below 10MHz. The output stage continues to hold these levels low even as the fundamental power reaches higher levels. As with most op amps, the spurious intermodulation powers do not increase as predicted by a traditional intercept model. As the fundamental power level increases, the dynamic range does not decrease significantly. For two tones centered at 10MHz, with -2 dBm/tone into a matched 50 Ω load (that is, 0.5V_{PP} for each tone at the load, which requires 2V_{PP} for the overall two-tone envelope at the output pin), the [Typical Characteristics](#) show a 96dBc difference between the test tones and the third-order intermodulation spurious levels. This exceptional performance improves further when operating at lower frequencies and/or higher load impedances.

Board Layout

Achieving optimum performance with a high-frequency amplifier such as the OPA659 requires careful attention to PCB layout parasitics and external component types. Recommendations that can optimize device performance include the following.

a) Minimize parasitic capacitance to any ac ground for all of the signal input/output (I/O) pins. Parasitic capacitance on the output and inverting input pins can cause instability: on the noninverting input, it can react with the source impedance to cause unintentional band-limiting. To reduce unwanted capacitance, a window around the signal I/O pins should be opened in all of the ground and power planes around those pins. Otherwise, ground and power planes should be unbroken elsewhere on the board.

b) Minimize the distance (less than 0.25in, or 6.35mm) from the power-supply pins to the high-frequency, 0.1 μ F decoupling capacitors. At the device pins, the ground and power plane layout should not be in close proximity to the signal I/O pins. Use a single point ground, located away from the input pins, for the positive and negative supply high-frequency, 0.1 μ F decoupling capacitors. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections should always be decoupled with these capacitors. Larger (2.2 μ F to 10 μ F) decoupling capacitors, effective at lower frequencies, should also be used on the supply pins. These larger capacitors may be placed somewhat farther from the device and may be shared among several devices in the same area of the PCB.

c) Careful selection and placement of external components preserves the high-frequency performance of the OPA659. Resistors should be a very low reactance type. Surface-mount resistors work best and allow a tighter overall layout. Metal film and carbon composition, axially-leaded resistors can also provide good high-frequency performance. Again, keep the leads and PCB trace length as short as possible. Never use wirewound-type resistors in a high-frequency application. The inverting input pin is the most sensitive to parasitic capacitance; consequently, always position the feedback resistor as close to the negative input as possible. The output is also sensitive to parasitic capacitance; therefore, position a series output resistor (in this case, R_{ISO}) as close to the output pin as possible.

Other network components, such as noninverting input termination resistors, should also be placed close to the package. Even with a low parasitic capacitance, excessively high resistor values can create significant time constants that can degrade

device performance. Good axial metal film or surface-mount resistors have approximately 0.2pF in shunt with the resistor. For resistor values greater than 1.5k Ω , this parasitic capacitance can add a pole and/or zero below 500MHz that can affect circuit operation. Keep resistor values as low as possible, consistent with load driving considerations. It is recommended to keep $R_F \parallel R_G$ less than 250 Ω . This low value ensures that the resistor noise terms remain low, and minimizes the effects of the parasitic capacitance. Transimpedance applications (for example, see [Figure 37](#)) can use the feedback resistor required by the application as long as the feedback compensation capacitor is set given consideration to all parasitic capacitance terms on the inverting node.

d) Connections to other wideband devices on the board may be made with short direct traces or through onboard transmission lines. For short connections, consider the trace and the input to the next device as a lumped capacitive load. Relatively wide traces (50mils to 100mils, or 1.27cm to 2.54cm) should be used. Estimate the total capacitive load and set R_{ISO} from the plot of *Recommended R_{ISO} vs Capacitive Load* ([Figure 24](#)). Low parasitic capacitive loads (less than 5pF) may not need an R_{ISO} because the OPA659 is nominally compensated to operate with a 2pF parasitic load.

Higher parasitic capacitive loads without an R_{ISO} are allowed as the signal gain increases (increasing the unloaded phase margin). If a long trace is required, and the 6dB signal loss intrinsic to a doubly-terminated transmission line is acceptable, implement a matched impedance transmission line using microstrip or stripline techniques (consult an ECL design handbook for microstrip and stripline layout techniques). A 50 Ω environment is normally not necessary onboard, and in fact a higher impedance environment improves distortion as shown in the distortion versus load plots. With a characteristic board trace impedance defined based on board material and trace dimensions, a matching series resistor into the trace from the output of the OPA659 is used as well as a terminating shunt resistor at the input of the destination device. Remember also that the terminating impedance is the parallel combination of the shunt resistor and the input impedance of the destination device: this total effective impedance should be set to match the trace impedance. If the 6dB attenuation of a doubly-terminated transmission line is unacceptable, a long trace can be series-terminated at the source end only. Treat the trace as a capacitive load in this case, and set the series resistor value as shown in the plot of *R_{ISO} vs Capacitive Load* ([Figure 24](#)). This configuration does not preserve signal integrity as

well as a doubly-terminated line. If the input impedance of the destination device is low, there will be some signal attenuation as a result of the voltage divider formed by the series output into the terminating impedance.

e) Socketing a high-speed part such as the OPA659 is not recommended. The additional lead length and pin-to-pin capacitance introduced by the socket can create an extremely troublesome parasitic network that can make it almost impossible to achieve a smooth, stable frequency response. Best results are obtained by soldering the OPA659 directly onto the board.

f) The thermal slug on bottom of OPA659 DRB package must be tied to the most negative supply. The DRB package is a PowerPAD thermally-enhanced package. Best results are obtained by soldering the exposed metal tab on the bottom of the OPA659 DRB directly to a metal plane on the PCB that is connected to the most negative supply voltage of the op amp. General layout guidelines can be found in the application reports, *PowerPAD™ Layout Guidelines* (SLOA120) and *PowerPAD™ Made Easy* (SLMA004), both available for download from the TI web site at www.ti.com. It may also be helpful to copy the EVM layout shown in the [Evaluation Module](#) section.

PowerPAD™ Information

The DRB package option is a PowerPAD™ package that includes a thermal pad for increased thermal performance. When using this package, it is recommended to distribute the negative supply as a power plane, and tie the PowerPAD to this supply with multiple vias for proper power dissipation. For proper operation, the PowerPAD must be tied to the most negative supply voltage. It is recommended to use five evenly-spaced vias under the device as

shown in the EVM layer views (see [Figure 41](#)). For more general data and detailed information about the PowerPAD package, refer to the *PowerPAD™ Thermally Enhanced Package* application note (SLMA002).

Input and ESD Protection

The OPA659 is built using a very high-speed complementary bipolar process. The internal junction breakdown voltages are relatively low for these very small geometry devices. These breakdowns are reflected in the [Absolute Maximum Ratings](#) table. All device pins are protected with internal ESD protection diodes to the power supplies, as [Figure 39](#) shows.

Figure 39. Internal ESD Protection

These diodes provide moderate protection to input overdrive voltages above the supplies as well. The protection diodes can typically support 30mA continuous current. Where higher currents are possible (for example, in systems with $\pm 12V$ supply parts driving into the OPA659), current limiting series resistors should be added into the two inputs. Keep these resistor values as low as possible because high values degrade both noise performance and frequency response.

EVALUATION MODULE

Schematic and PCB Layout

Figure 40 is the OPA659EVM schematic. Layers 1 through 4 of the PCB are shown in Figure 41. It is recommended to follow the layout of the external components near to the amplifier, ground plane construction, and power routing as closely as possible.

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46C and to discontinue any product or service per JESD48B. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components which meet ISO/TS16949 requirements, mainly for automotive use. Components which have not been so designated are neither designed nor intended for automotive use; and TI will not be responsible for any failure of such components to meet such requirements.
